Signal Codes and Machine Codes 38
Franz Pichler

Works in the Exhibition 42

Editorial

To understand the world
we inhabit.
To understand the world
we live in.
To understand the world
that sustains us.

Today we live significant portions of our lives in an artificial, human-made world of data. Digital codes provide access to this world. When we turn on a mobile phone, for example, we are immediately confronted with the prompt "enter passcode." In Paris it is also commonplace to get into a house or room by entering a numerical code at the door. Codes are crucial keys for access to our contemporary world, both analogue and digital.

The oldest codes in our culture include alphabets and numeral systems. In communication studies, a language is designated as a code in the broadest sense. All communication rests on the exchange of information generated by the sender using a given code and interpreted by the recipient according to the same code. More generally speaking, then, a code is based on a character set; it forms the instructions for depiction so that the characters of one character set can be clearly assigned to those of another. For example, the stream of sounds of the spoken English language can be assigned to the 26 letters of the Latin alphabet in order to represent the spoken vowels and consonants in writing. This visual alphabetical code of 26 letters can, in turn, through the use of short and long sound signals, be translated into Morse code. The essential characteristic of a code, then, is its translatability from one code to another. But what is most astonishing is that a virtually unlimited number of sentences can be produced from either the 26 letters of the Latin alphabet or the three signs of Morse code (short signal, long signal, pause), that is to say, a potentially infinite amount of information can be coded.

Morse Code

The signals of Morse code are transmitted via an electromagnetic telegraph. These characters can be sent as sound or radio signals, as an electrical impulse via a telephone line through the interruption of a constant signal with a button, or optically by switching a light on and off. Morse code fundamentally consists of two states, the signal and the pause, and a temporally variable signal length. This transmission method is called Morse telegraphy. It was named after the painter and inventor Samuel Morse, who constructed the first model of a functional electromagnetic telegraph in 1833. Initially it was only able to transmit ten digits, which were translated into letters and numbers according to a coding chart (a = · –). In a later, more developed form, standardized Morse code provided the vital radio technology for seafarers.

Numerical Code

While the alphabetical code predominated as the primary code for human culture and communication for thousands of years, today numerical code dominates our world, as the examples cited above show. This code essentially consists of the ten numerals 1 to 9 and 0, through which an almost infinite number of numbers can be formed. In 1697, Gottfried Wilhelm Leibniz achieved for numerical code something similar to what Morse would later achieve for alphabetical code.[1] Leibniz proved that all numbers can be represented by just two digits, 0 and 1. He did not take words, images or numbers as counterparts for objects as was usual, but rather allocated digits to numbers for the first time: "Numbers can be used to express all kinds of true sentences and deductions" (Leibniz, *De progressione dyadica*, 1679) Leibniz's binary number system, his binary code, with which he began to translate words and sentences into numbers, was a prerequisite for the digital code of today.

As all information in the digital world is processed as numbers, letters of the alphabet and numerals are depicted as bit sequences in the computer. The combinations of 0 and 1 (bits) can be stated as numbers, signs or letters (e.g., a = 1100 0001, b = 1100 0010). In coding theory, the elements that make up the code are called "code words," and the symbols that make up the code words are called the "alphabet." Whereas until recently, the code systems of language and writing served the purposes of communication between people, today many code systems are available which also enable people to communicate with machines and things. These include the bar codes and QR codes of merchandise management, as well as the important ASCII (American Standard Code for Information Interchange), which is used for coding character sets.

In computer science, the text of a computer program that is written in a programming language in a way that is legible to people is called source code, source text, or program code. It is created according to the rules of the respective programming language. Source code is often written in ASCII code. In order for the computer to execute the source code, it has to be converted into machine language, that is, into commands that can be executed by a processor.

On the History of Digitization

Important twentieth-century philosophical books bear titles such as *Word and Object* (Willard Van Orman Quine, 1960) and *Les Mots et les choses* (Michel Foucault, 1966)[2]. These books tell of an analogue world that consists primarily of things and of the relationship between things and words. Thus in these texts, language is the instrument that orders the world. Hence Ludwig Wittgenstein's famous dictum, "The limits of my language mean the limits of my world."[3]

Indeed, language was the first tool which enabled people to explain and shape the world. People gave names to things, and these relations between words and things were decisive for culture and civilization for thousands of years. Just as people gave names to things, they also assigned pictures to things, which gave rise to a second cultural technology; the art of imagery, from painting to photography. The things also generated sounds; moreover, people even created new things especially to produce sounds.

The world of images, words, and sounds was soon joined by the world of numbers. Mathematics is the world of numbers. The evolution of digitization proceeded in three stages. The first stage of digitization, or rather the mathematization of the world, began with the mathematization of physics. In 1623, Galileo Galilei wrote, "Nature is a book written in the language of mathematics."[4] Depicting things in words and images in itself represents a considerable level of human abstraction. Expressing the world in numbers which took on a life of its own as mathematics, was the as yet highest stage of a cultural technology that distinguished people from all other living creatures. This increased abstraction through mathematics and the development of the natural sciences as mathematical disciplines digitization began in the proper sense 400 years ago. Mathematics became a universal language.

To put it simply and schematically: in the seventeenth and eighteenth centuries the mathematization of physics took place (1st stage), and in the nineteenth and first half of the twentieth century the mathematization of thought (2nd stage). In the latter half of the twentieth century both tendencies converged in the development of electronics (3rd stage). In his monumental

Philosophiae Naturalis Principia Mathematica of 1686, Isaac Newton laid the foundations for describing nature in mathematical terms. Joseph-Louis de Lagrange's 1788 masterpiece *Méchanique analytique* was the first work to offer a full description of the universe on the basis of pure algebraic operations. He carried physics over into analytical mathematics. Lagrange algebraized mathematics and mathematized physics. This algebraization of physics led to the second stage of digitization: the algebraization of logic (of formal thought). Logical forms were captured with the aid of mathematical methods and terms. As a response to Newton's *Principia*, Bertrand Russell and Alfred North Whitehead published their three-volume work *Principia Mathematica*, 1910–1913. Like Gottlob Frege, who used his 1879 work *Begriffsschrift. Eine der arithmetischen nachgebildete Formelsprache des reinen Denkens* to translate thought into mathematical formulas, Russell and Whitehead portrayed thinking and logic in mathematical terms.

A milestone was set by George Boole who defined the laws of thinking as laws of formal logic and these in turn, building on Lagrange, as algebraic mathematics. In *The Mathematical Analysis of Logic* (1847) and *An Investigation of the Laws of Thought* (1854), Boole proved that logic and algebra are identical by expressing logical statements as algebraic equations. Alan Turing, ultimately, brought these tendencies to mathematize the world, language, and thought to their culmination in his famous 1936 essay "On Computable Numbers." Turing's depiction of the calculability of numbers and number processes is considered the foundational paper for the development of the digital computer, for what is known as the Turing machine. Henceforth one no longer just calculated with numbers but rather numbers became calculable. With calculable numbers, nature becomes computable.

With the further development of the computer from a pure calculating machine to a machine of images, sound, and language, a new world of data emerged. Images and texts can be computed and visual and acoustic worlds can be simulated. In a word, everything that was previously made up of objects, words, sounds, and images can be represented in numbers and constructed from numbers. The crucial aspect of this digital cultural technology is a hitherto unimaginable reversibility. In the analogue world the principle of irreversibility prevails in the relationship between things and words or images. Things can be transformed into words, but not words can be retransformed into things, because the word "chair" is not actually a chair. Things can be transformed into images, but not images into thing, because the picture of a pipe is not a pipe, to cite René Magritte's 1929 painting *La trahison des images*, which displays the image of a pipe and below it the words *Ceci n'est pas une pipe* – this is not a pipe. In the era of digitization, words, images and sounds are transformed into data, and – for the first time in human history – this data can be transformed

back into sounds, images, and words. And with 3-D printing data can even be transformed into things. The relation between data and things, words, images are reversible. The language of data, algorithms, and programming languages has become a universal language out of which the world of sounds, images, texts, and things emerges. Thus mathematics has long since ceased to be just the language of nature; it has become the language of culture. The book that describes the contemporary world must be titled *The Things and the Data*. The relationship between things, words, and images used to be irreversible. However, now the relationships between data and words, images and sounds are reversible in the digital world.

Digital Codes

Digital cultural technology, however, has also provided the foundations for another revolution, which will possibly usher in a new era. Culture to date has been based on two-dimensional notation: notes, numbers, and signs on paper are notated and fixed just like writing. The computer, however, enables the simulation of moving three-dimensional spaces, and in this way enables a future, three-dimensional notation which is already being used today by architects and designers. 3-D cinema was the first attempt along these lines, but it is with 3-D printing that this future begins to become a reality through the aforementioned possibilities of reversible transformations. Thanks to the development of this cultural technology, which renders the relationship between the worlds of things and signs reversible, we will live in an environment that is underpinned by sensors and intelligent agents, managed by codes and algorithms, and equipped with artificial intelligence.

The fact that this has become possible goes back to "The Unreasonable Effectiveness of Mathematics in the Natural Sciences," which was ascertained by Nobel Laureate Eugene Wigner in 1960. Reality is what can be expressed mathematically and electronically controlled. The best example of this is Claude E. Shannon's 1937 master's thesis, *A Symbolic Analysis of Relay and Switching Circuits*. In this work, Shannon proved that Boolean propositional logic can be used with the logical values 0 and 1 to control a remote-controlled switch with two switch positions that acts electromagnetically and is operated by an electric current. As the title of his work conveys, relay and switching circuits, arrangements of relays and switches, are mapped onto Boolean propositional logic in a symbolic analysis. Boolean logic thus becomes switching algebra. The linking together of the rules of logic with the controlling of switching circuits, that is, the use of the binary qualities of electrical switching circuits (on – off, 1 – 0, electricity – no electricity) to execute logical operations, henceforth

became definitive for the construction of all electronic digital computers. Shannon showed that the mental formulas of Boolean algebra could be transformed into material switching algebra. Formal thought was carried over into electronic switching circuits according to the rules of Boolean algebra. Electronics became the physics of mathematics.

In connection with the discovery of electromagnetic waves by Heinrich Hertz (1886–1888), that is, the invention of telecommunications (the telegraph, the telephone, television, radar, radio, satellites, the internet) and the development of transistors (1947), integrated circuits, and microchips, over the last century the mathematization of the world became transferable to the material world of electronics. Thus the equation of "Machinery, materials, and men" (Frank Lloyd Wright, 1930), which applied to the nineteenth and twentieth centuries, had to be expanded to "Media, data and men" (Peter Weibel, 2011) for the twenty-first. After alphabetical code was supplemented by numerical code, algorithms now represent a fundamental element of our social order.

The Concept of the Exhibition – An Experiment in Education

By means of some 200 artistic and scientific works, the exhibition displays the world of digital codes and the future forms of life influenced by them in eight areas: #GenealogyOfCode, #Encoding, #MachineLearning, #AlgorithmicGovernance, #Algorithmic-Economy, #VirtualReality, #Labor&Production, and #Genetic-Code. The works presented offer you the chance of trying out an unusual way of engaging with art and defining your own exhibition visit a bit. Unlike with the conventional reception of analogue paintings, sculptures, and installations, the horizon of meaning in *Open Codes* is only revealed in the process of observers physical interacting with the works. The participation of the audience is the moment when the works come into being materially. Participatory and analytical engagement with the works therefore includes new forms of concentration and meditation as well as divertissement. The *discours* of the exhibition is arranged as an architectural *parcours* so that you have the opportunity to stroll around autonomously among islands of art and knowledge or to be active and creative at the places called "work stations," that is, to converse with other people or to take a break and rest. Because the works unfold in a particularly fascinating way when observed for a longer period of time and we want you to explore the works intensively, we are providing drinks and snacks free of charge. Admission to the exhibition is free – and you will experience a combination of a laboratory and a lounge, a learning environment and park oasis.

It is clear that in this exhibition architectonic concept and scenography depart radically from the usual museum set-up of

the White Cube. Elements of a studio, a laboratory, and the home alternate, from a glowing cloud to programmable music machines. The museum as the Commons: the museum becomes an open source community in which people collaborate and become more competent, creative, and knowledgeable together. On the one hand, the architecture is designed to evoke the atmosphere of a space for making, doing, and co-working. On the other hand, the walls are positioned so that they create organic forms. Here the museum becomes a place of community education where the acquisition of knowledge is not only rewarding, but is also rewarded. For the real message of digital transformation is: The society of tomorrow will (have to) change from a work-based society to a knowledge-based society. Thus we demand access to free civic education in the twenty-first century! It is imperative we have culturally competent citizens in order to defend democracy.

The ZKM | Museum Communication team has therefore developed innovative learning concepts with the goal of opening up the intriguing world of digital coding for people of all ages. The wide-ranging communications program offers suitable formats for everyone: small children and (grand)parents, hackers and artists, computer scientists and coding amateurs. You can explore digital coding in theory and in practice directly in the exhibition spaces together with active participants from Karlsruhe and ZKM employees – at workshops, parties, camps, algoraves, science slams, experimental tours, or programming courses.

Open Codes 101

Exhibition Manual

We live in an age where knowledge production, dissemination, and acquisition are changing on a global scale due to the ongoing evolution of technologies based on codes. Of central importance in these debates is the position and purpose of a museum in this day and age. When you hear the word "museum," you probably think of its institutional remit to collect, preserve, and exhibit historical artifacts and/or artworks. With the exhibition *Open Codes* we are proposing a new definition of the museum for the twenty-first century which breaks with rigid structures and outdated attitudes: Our goal is to address present-day challenges and needs and integrate them into the museum. It is an attempt to engage with today's realities and point up perspectives and lines of development for the future in order to better understand the world we live in.

To this end, we have developed a deinstitutionalized format, a platform of knowledge to which access is always free, and which resembles closely the actual worlds in which we live and work. *Open Codes* is designed as a communal space, as an environment in which people come together and exchange ideas, views, information, and experiences. Working and learning are understood as collaborative processes to create synergies between different professions and various forms of knowledge and expertise. You, the visitors, are invited to work, produce, and learn together with others. The design of the exhibition, which is interspersed by park-like oases for relaxing, spaces for focused working, office spaces, and play areas, aspires to promote competence, creativity, and acquisition of knowledge. *Open Codes* is a platform that facilitates collaboration and co-creation; which invites you to participate in open exchange within an environment that undergoes constant change. In the exhibition various approaches are tried out to test new forms of encounter and critical debate. You will get to know a very new kind of environment where knowledge can be accessed; it is a place that continuously changes, re-configures, develops, and evolves.

A part of this concept are various tools that you can use to address the exhibition:

Hashtags

The many topics dealt with in the exhibition are grouped in eight key areas:
#GenealogyOfCode
#Encoding
#MachineLearning
#AlgorithmicGovernance
#Labor&Production
#AlgorithmicEconomy
#VirtualReality
#GeneticCode

A distinguishing feature of the exhibition is that the artworks are not physically grouped according to themes. The overarching topics are presented as title hashtags together with other hashtags associated with these topics. This allows you to draw connections among the different themes. Each artwork is assigned several hashtags.

This hashtag system is similar to how hashtags are used in the media, and thus represents for the open, flowing, and dynamic connections between themes that is so characteristic of our networked world.

The # character was used to denote a number – e.g., # 2 instead of no. 2 – until 2007, when social media users began to use it as a metadata tag to sort content related to specific keywords. It is now a dynamic, association-based classification system, widely used in social media for arranging content, discussions, and themes in specific categories. Through hashtags being combined with content, images, videos, etc., a non-hierarchical system results that resembles a cloud: all kinds of content can be associated with very different keywords, and do not fall under just one specific and exclusive category.

The hashtag began its triumphant advance on Twitter ten years ago, when the platform began to hyperlink all hashtagged terms in tweets to Twitter search results for the hashtagged word. When Instagram launched in 2010, the hashtag became the lingua franca for labeling content on both platforms. Now it can be found on any online platform, and it influences the way we search and access information online.

The Brochure

The brochure you are holding in your hands is one of the main tools for navigating the exhibition. In addition to this text about

the exhibition and its components, it contains an introduction by the exhibition's curator, Peter Weibel, texts describing the eight thematic areas, a text on the subject of signal codes and machine codes by Franz Pichler, and a list of the artworks on show.

Descriptions of the artworks are displayed next to them in the exhibition and are also available on the exhibition website.

If you wish to focus on a particular key theme (title hashtag) of the exhibition in more detail, you can refer to the accompanying leaflet with the floorplans of the exhibition. There you will find a map of each thematic complex as well as an overview of the entire exhibition. This is the quickest way to see where specific works can be found in the exhibition.

The App

You can also navigate the exhibition by using the *experience_zkm* app, which is available for Android and Apple devices. With this app you can start a keyword search for one of the title hashtags and you can hear the particular text as an audio file while the artworks flagged that are associated with that particular theme will be highlighted on the exhibition map.

The app also has a few special features: Throughout the exhibition you will see markers on the floor. When you approach one, the app will send you a notification, and if you approach an interactive artwork, your smartphone will supply instructions of how you can interact with the work. This feature can be turned off.

Info Points and Website

In addition to the Brochure and the App we have put together an extensive online resource of information which includes descriptions of the artworks, images, as well as a great deal of background material – journal and newspaper articles, videos, further reading –, and other artworks that are only available online. You can access this information via the main ZKM website (https://open-codes.zkm.de) from your own devices or at the Info Points in the gallery space.

Work Stations

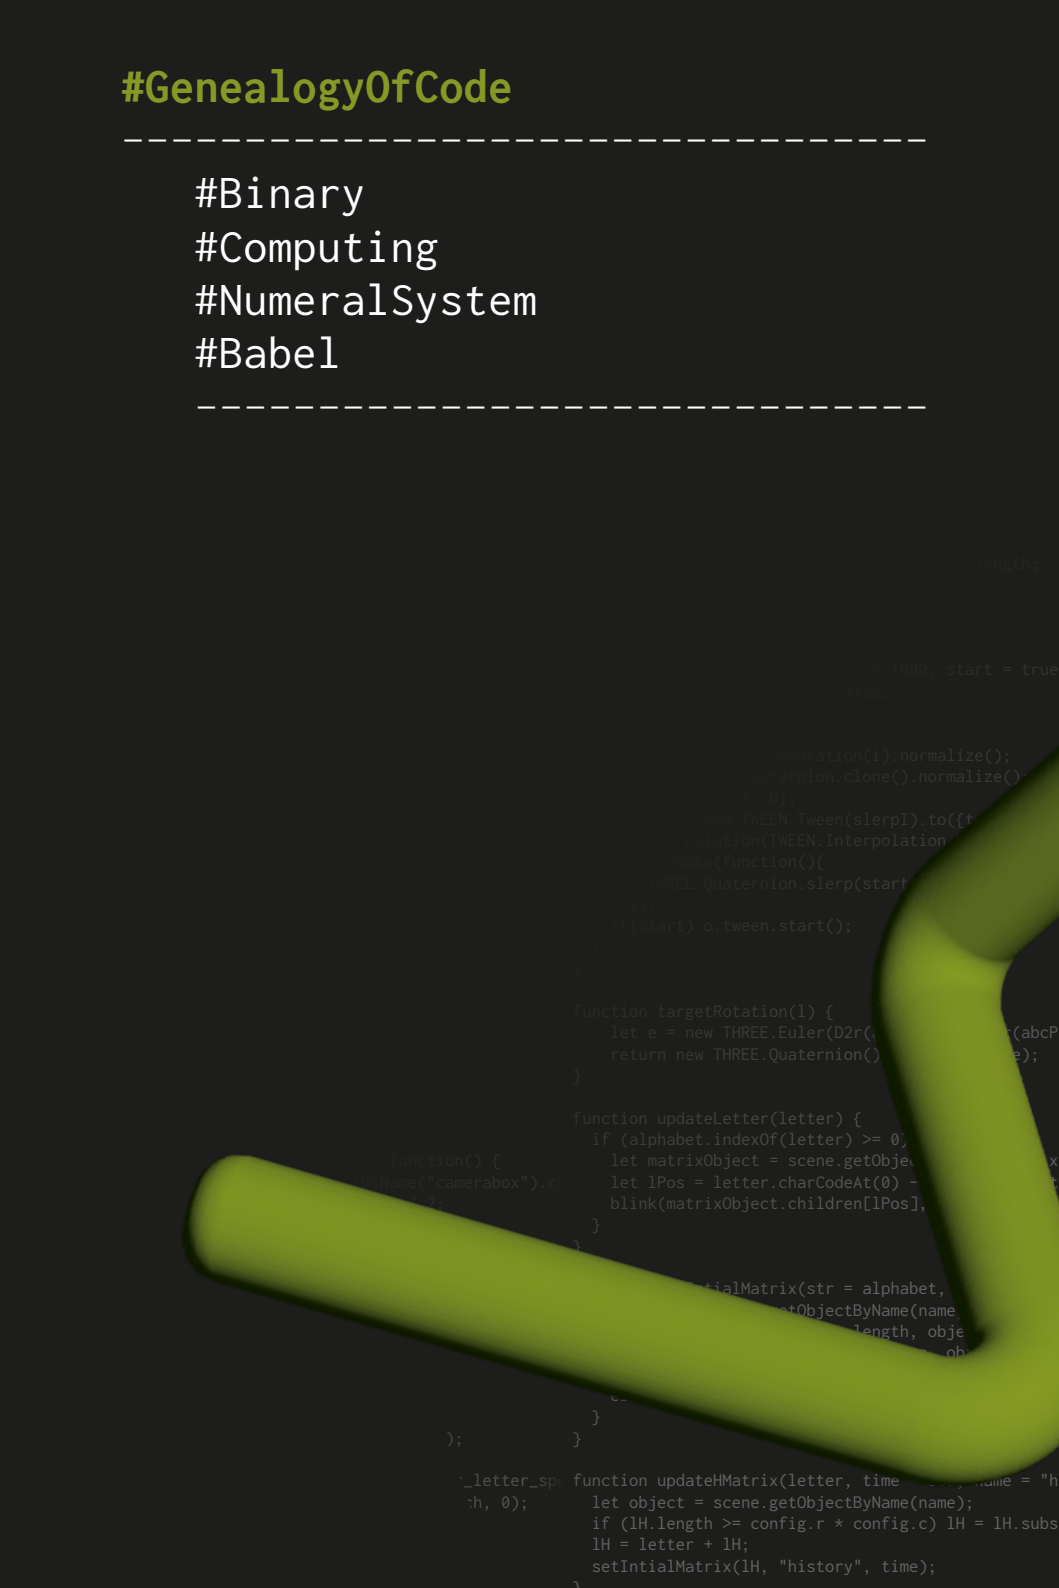
All over the exhibition you will find tables and work stations where you can sit down at any time to read, write something down, code, or do anything else you feel inspired to do. The work stations are there to let you give free rein to your imagination so that you don't have a long search for somewhere to put down your ideas. In these areas you can work by yourself or in a group. Some of the work stations are designed as co-working spaces and facilitate exchanges between very different people and interests.

Other work stations are more quiet environments conducive to concentration and focused work. To whet your appetite for learning, to reward your educational competence, non-vending machines provide drinks and snacks, fruit, etc. absolutely free of charge.

The working area in Atrium 8 is of a different kind; it is designed so that various public events can take place there. Workshops, lectures, and roundtable discussions will be held and everyone is invited to participate and get involved. The important thing about this space is that *you* can shape its content. We provide the infrastructure; you fill it with ideas. If you would like to hold or organize an event here, just visit our website to book the spaces at the desired date.

#GenealogyOfCode

#Binary
#Computing
#NumeralSystem
#Babel



Computation clearly does not begin with personal computers and their direct ancestors from the twentieth century. To find the roots of the principles upon which computation of today is based on one has to go back at least to the Middle Ages.

Ramon Llull (1232–1316), a Majorcan thinker, sought to develop a system for solving basic theological and philosophical questions, a method by means of which he tried to find and explore all possible combinations of concepts with the help of dynamic charts. This procedure, his so-called Ars magna [Great Art], is explained most extensively in his notable work *Ars magna* (1274–1308).[1] Gottfried Wilhelm Leibniz (1646–1716) conceived his *Dissertatio de arte combinatoria* [Dissertation on the Art of Combinatorics] (1666), in which he proposes a parallelism between logic and metaphysics inspired by Llull.[2]

In 1679 Leibniz wrote about a #Binary system ("dyadic" or "binaria arithmetica") in one of his unpublished letters, which uses only 0 and 1 as numbers. He was not sure about the practical use of his invention, but frequently wrote about its possibilities in various letters to his colleagues. In 1701 he claimed to a French mathematician that he imagined to foresee, that by this means and the endless rows there is something to achieve, which wouldn't be easy in another way. Leibniz described the first computing device (#Computing) that works with the binary system as early as 1679. The description remained unpublished and the machine was not built in his lifetime.[3]

Two centuries later Charles Babbage was working on his Difference Engine, followed by the Analytical Engine, neither of which were constructed entirely under his guidance due to insufficient funding. The Analytical Engine would have been the first general purpose computer, but still a mechanical one. "The bounds of *arithmetic* were, however, outstepped the moment the idea of applying the cards had occurred; and the Analytical Engine does not occupy common ground with mere 'calculating machines'"[4], wrote Ada Lovelace (1815–1852), acknowledged today as the first programmer, in her notes on Babbage's computing automaton. This early device operated with a decimal #NumeralSystem. Computers nowadays are based only on a binary numeral system, first used by Leibniz, then reintroduced by George Boole (1815–1864).

Boole first cast logic into algebraic form in his book *The Mathematical Analysis of Logic* (1847), introducing the Boolean algebra.[5] Boole's binary system is based on the three most basic operations used as logical operations: AND, OR, and NOT.[6]

This system was not put into operation until "Claude Shannon, in 1937, proved in what is probably the most consequential M.A. thesis ever written, that simple telegraph switching relays can implement, by means of their different interconnections, the whole Boolean algebra."[7]

Also in 1937, Alan Turing (1912–1954) built a Boolean logic multiplier and proposed a theory of computability in his essay on the "Entscheidungsproblem" [decision problem].[8] The paper had already been written the previous year while he was working on his well-known Turing machine, which was not a physically existing computer, but a mathematical model of computation. With his multiplier based on Boolean logic, Turing tried "to embody the logical design of a Turing machine in a network of relay-operated switches",[9] which served as a basis for creating the multiplier.

Soon after, from the 1940s with the appearance of electronically powered computers, different programming languages were designed and assembler (asm) was one of the first. This low-level programming language can be converted into executable machine code in one step, as there is a very strong correspondence between the language and the machine code. From the 1950s onward high-level programming languages started to replace their "low" antecedents. Dozens of programming languages have been written and developed, starting with ALGOL (ALGOrithmic Language), then Fortran, Pascal, C++, Java, and Python, to name just a few. "This postmodern Tower of Babel reaches from simple operation codes whose linguistic extension is still hardware configuration, passing through an assembler whose extension is this very opcode, up to high-level programming languages whose extension is that very assembler."[10] (#Babel)

All these languages are based on a binary number system, a sequence of "ons" and "offs" allowing electricity in the circuit to flow or stop. Despite the simplicity of their basic components, programming languages can describe exceedingly complex operations. The computing devices mentioned above all run with binary code, except Babbage's machines, which used the decimal system. Due to Shannon's work and the implementation of transistors binary systems became ubiquitous in computing.

In addition to algorithms (see #Algorithm in key area #Encoding) and calculations anything decodable can be described by binary code. Perhaps the best-known example is ASCII (American Standard Code for Information Interchange), the characters displayed on a computer screen, which was developed from telegraph code beginning in 1960.

The capacities of current computers may not be sufficient for the amount and complexity of computing in the future. The development of modern computers has been very fast, which is even more striking when compared to the improved performance of cars. If cars made in 1971 had improved at the same rate as computer chips, then by 2015 new models would have had top speeds of about 680 million kilometers per hour.[11]

Quantum computing could be the answer to the recent and seemingly inevitable expansion.

In a quantum computer logical operations are performed on an atomic level. Atoms register more than bits, they are able to register 0 and 1 at the same time, and thus quantum bits or qubits are more efficient than classical bits because they can perform two computations simultaneously.[12]

"How long can computation continue in the universe? Current observational evidence suggests that the universe will expand forever. As it expands, the number of ops performed and the number of bits available within the horizon will continue to grow."[13]

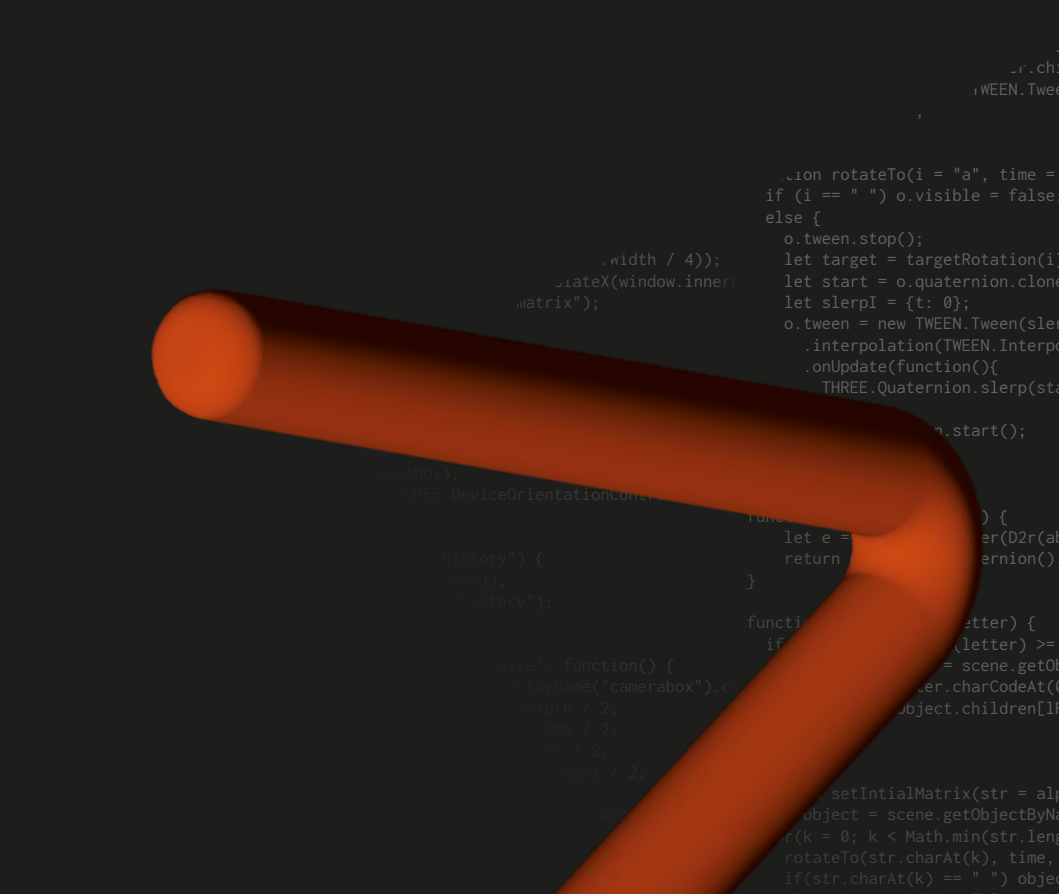
#Encoding

#MorseCode
#ProgrammingSound
#Algorithm
#Software
#Hardware
#Interface
#Decoding



From #GeneticCode (see correlating key area) to music notation, from communication systems for sensory impairments, such as sign language, to #MorseCode, from safety codes and standards to social rules of conduct, the term "code" may outwardly designate recognizable elements and familiar processes, but what does it mean in terms of #Programming (see key area #Labor&Production) and computing?

The *Dictionary of Computing* defines code as "a rule for transforming a message from one symbolic form (the source alphabet) into another (the target alphabet)."[1] Therefore, code could be seen as a set of instructions "that changes the input from one state to another, and as a consequence the code performs work."[2] This way of performing designates precisely one of its main characteristics: code is at the same time legible and executable; it is simultaneously a medium and an instruction. This essential virtue makes code different from common languages, which can be read or written but do not cause any changes by doing this per se. In that sense, computer code "is the first language that actually does what it says – it is a machine for converting meaning into action."[3]

Another crucial aspect of computer code is its deceptive invisibility. Code is generally hidden; it lacks materiality in itself and remains mostly unseen inside the machine, but it generates visible, concrete, and tangible effects in the world. Taking a programmed sound work as an example, the different sounds or compositions would be the output, in other words, the result of one or many lines of code (#ProgrammingSound).

Similarly to code, the word #Algorithm is often associated with computing and programming, although the definition of algorithm, being a sequence of actions to be performed, could be applied for various procedures. An algorithm is a set of rules that specify how to solve a problem or perform a task. In that sense, a recipe or a manual of production could be understood as an algorithm, too. In computing, these sets of rules or steps are established in order to process data and, as we have already seen, produce an output.

Algorithms and code are also the invisible part, commonly summarized under the term #Software, which is "a generic term for those components of a computer system that are intangible rather than physical."[4] By contrast, #Hardware is the compilation of physical components that form a computer system like, for example, the mainboard. In order that software and hardware can exchange information, a third element is needed, the #Interface, which also can be the link between software, hardware, and humans. To understand how this exchange works, we only have to think about a "power" button: the button is, namely, the interface

between you and the electrical wiring behind the machine. You press it and the machine turns on and off.

Even in common, ordinary applications such as sending an SMS, code executes an extremely high number of algorithmic operations. In computers, #Encoding is the process in which a sequence of characters is transformed into a specific format for efficient transmission or storage. In order to convert an encoded format back into the original sequence of characters, the opposite process, called #Decoding, would be necessary. Both processes are commonly used in data communications, networking, and storage, and especially with regard to wireless communications systems. By running these and other processes, code nowadays has the capacity to process and control many different operations within seconds, shaping and creating new horizons for social, economic, or cultural activity.

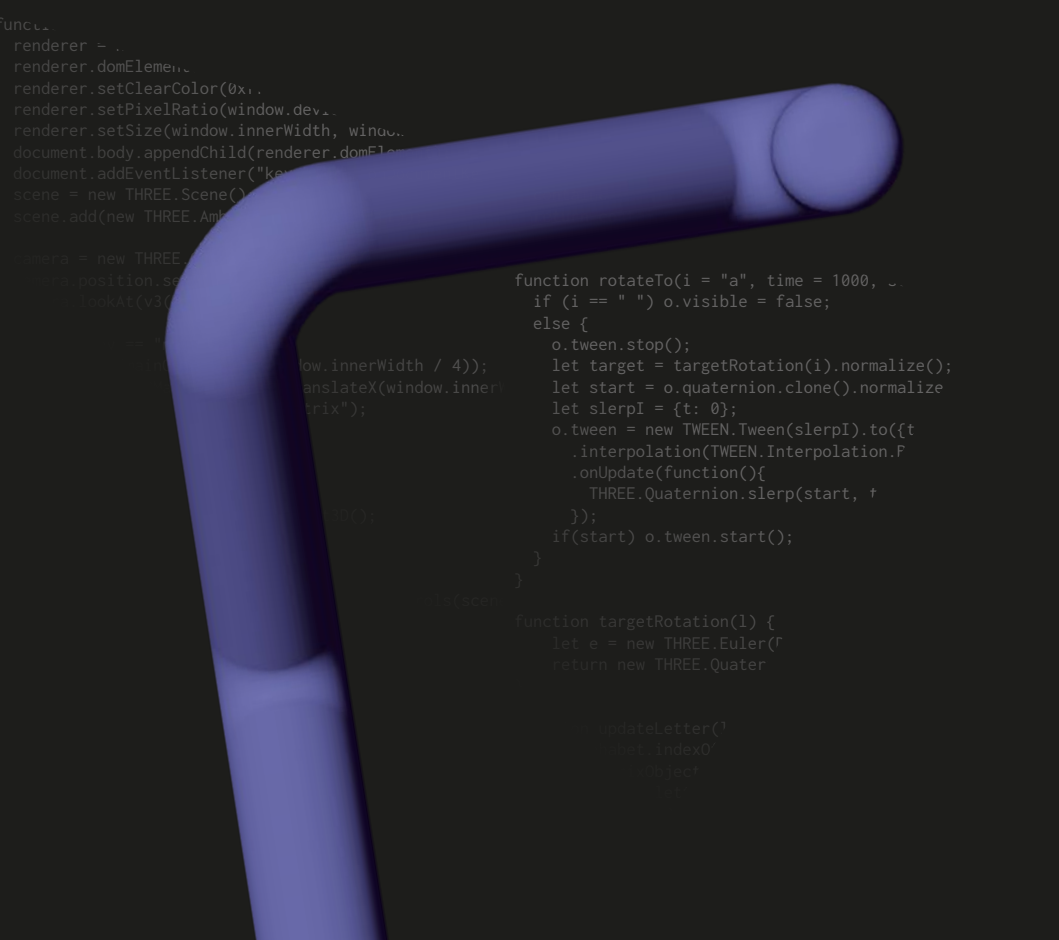
#MachineLearning

#ArtificialIntelligence
#Cybernetics
#PatternRecognition
#AutonomousSystems
#SelfDrivingCars
#Drones
#Robots



In computer science #ArtificialIntelligence (AI) determines the operations of intelligent agents using forms of mechanical or "formal" reasoning. AI was founded on the idea that a machine can simulate human intelligence. Alan Turing's theory of computation suggested that it was possible to represent logical operations by modifying simple symbols such as 0 and 1. Turing assumed that reasoning can be formalized as distinctive sequences of mechanical operations based on cause and effect – in other words, discrete sequences of logical steps based on a set of rules (#Algorithm, see key area #Encoding).[1] What came to be known as the classical symbolic approach to AI considers machine cognition as rule-governed manipulation of formal symbols with a centralized control mechanism. It was the attempt to code knowledge about the world in formal mathematical language. This approach was successful for so-called expert systems, which were able to carry out complex tasks, such as medical diagnosis, or planning and configuration at the level of human experts. However, they proved difficult to program since one simple error sometimes caused the whole system to fail. But most importantly the systems were not able to inherently learn.[2] By 1980 the approach was no longer pursued as it became clear that a mere simulation of thought does not amount to real understanding; therefore, that syntactic manipulation of symbols does not suffice for cognition.[3]

A more flexible and adaptive approach to machine cognition came from the field of neuroscience and #Cybernetics, where artificial intelligence was not treated in terms of rules and representations but as dynamic systems. Warren S. McCulloch and Walter Pitts' ground-breaking research was the first work that treated the brain as a computational apparatus.[4] Together with Donald O. Hebb's work on associative learning deriving from the firing of nodes that produce synaptic interrelations,[5] Frank Rosenblatt developed the foundation for machine learning.[6] #MachineLearning is a field of AI that explores forms of computation which allow programs to change and adjust its internal parameters automatically, that is, without hand engineering the algorithms, in order to process data. The algorithmic structure is constituted as an artificial neural network, whose reasoning is executed by thousands of neurons, arranged into hundreds of intricately interconnected layers breaking up causal relations. Neural computation is based on modelling an adaptive system that evolves through the capturing of environmental data, which is fed back into the system.[7] Crucially, the networks' output constitutes an approximation, a statistical likelihood for the most probable outcome.

Since 2006, machine learning has made huge leaps forward as a consequence of a steady increase in computational power coupled with the vast expansion of data capturing mechanisms and the

enlargement of the physical IT infrastructure.[8] In its practical application machine learning algorithms are heavily employed for #PatternRecognition; visual object recognition and object detection particularly relevant for #AutonomousSystems such as #SelfDrivingCars, #Drones, and #Robots. In essence, machine learning reconstitutes what thinking means and raises many ethical and legal questions with regard to automated decision-making, machine bias, liability, and accountability.

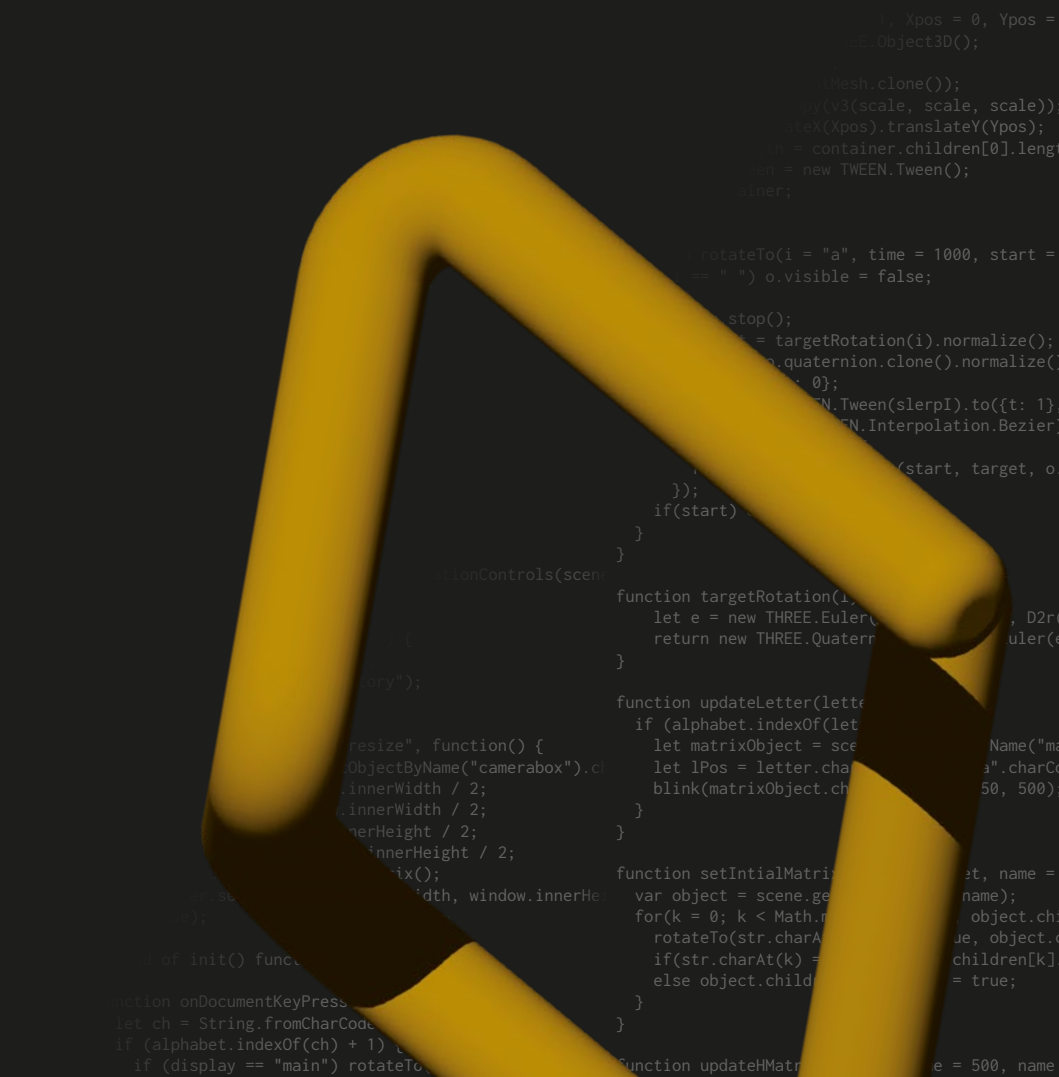
#AlgorithmicGovernance

#BigData
#QuantifiedSelf



Governance refers to a process of governing – the way in which norms, laws, and actions are structured, sustained, and held accountable, whether undertaken by the government, society, or the market economy. Essentially, governance involves the practice in which societies are organized, the logic or language of regulation. Hence governance also implies a way of exercising power over someone or something.[1] #AlgorithmicGovernance explores the formal and informal rules of organizing the living through #Algorithms (see key area #Encoding). Algorithmic governance refers to a form of soft power that interrupts habits and reorients action potentials. It is a producing force that generates the particular behavior that comes to the surface next; a force that acts before the behavior takes shape.[2] As such algorithmic governance offers a radically different form of managing all aspects of human life, be it socially, politically, economically, or environmentally. It raises immanent questions of how algorithmic processing should be regulated and legislated.

Underlying new forms of governance is the way in which data is gathered and analyzed in order to ascribe value. The last decade has seen an explosion in the amount of data that is being captured and processed in real time. Our environment is increasingly encoded (see key area #Encoding), rendered machine-readable, uniquely indexical, and identifiable by the vast assemblage of connected devices and sensors. Daily life is becoming more and more mediated by digital devices and facilitated by computational infrastructure. The #BigData undertaking strives at capturing society as a whole, the entirety of the population and its activities.[3] The endeavor of data collection and the quantification of the self (#QuantifiedSelf) is underpinned by the intention to produce sophisticated statistical models that characterize, simulate, and predict human life. The key to assembling all this data is the way in which information is correlated – the processing of data through various kinds of statistical analysis and #Machine-Learning algorithms – which detect patterns and connections between pieces of data. Correlations of data become sources of knowledge and/or information.

In consequence, governance seems to have turned into a struggle of *how* data is evaluated and *by whom*. Essentially, what the correlation of data allows for is the assemblage of profiles for individuals and groups of people to determine so-called normal behavior and distinguish the abnormal. Individuals are thereby turned into "dividuals," numerical bodies of code comprised of data assemblages.[4] On the basis of these profiles governments and businesses implement their agendas. Whereas the latter adopt strategies to realize capital accumulation that will produce significant profits, the concern of the former is state security.

With increasingly invasive means of profiling, companies seek on the one hand to personalize consumer behavior through micromarketing of products. On the other side stands the state which uses new technology to gather information that is supposed to prevent crime but at the same time can attempt to influence how the electorate votes through microtargeting. In both cases powerful algorithms in combination with predictive analytics are employed to conditions of life's nextness. Control is exercised subtly, making it seem as if the dividual is acting autonomously, yet it lacks the ability to make decisions of its own volition.

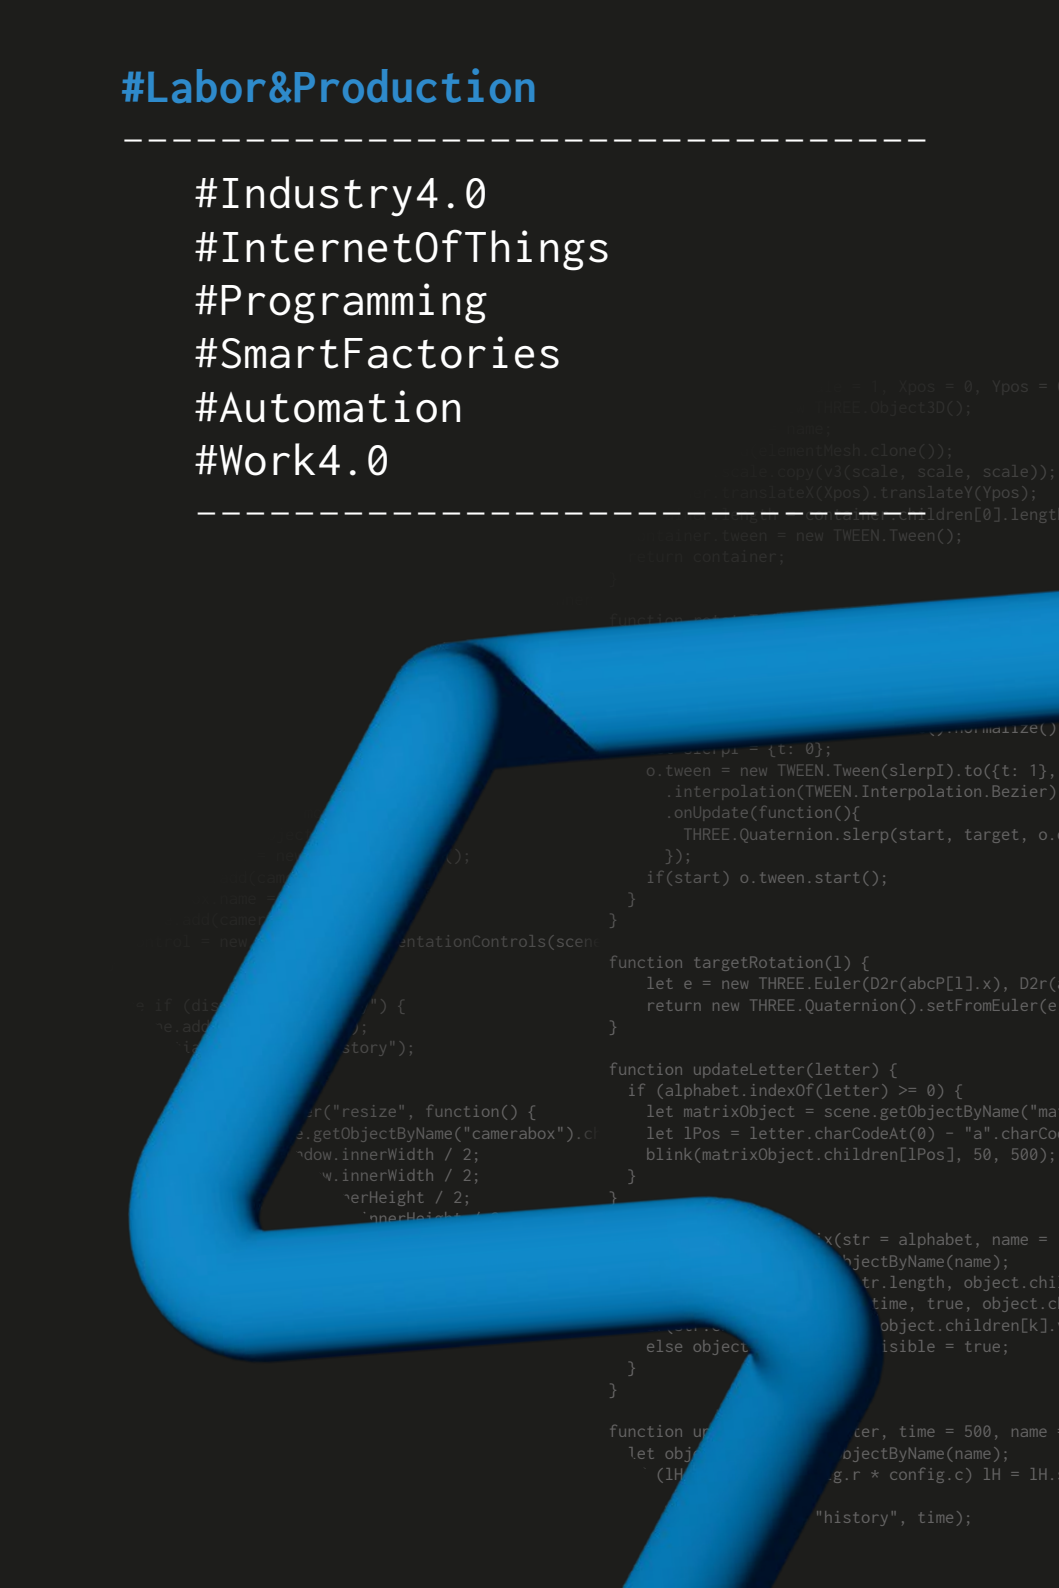
#Labor&Production

#Industry4.0
#InternetOfThings
#Programming
#SmartFactories
#Automation
#Work4.0



The desire for on demand goods and services, customized to one's personal tastes and available 24–7, is steadily increasing. It is a phenomenon of the digital economy, a business model that cuts across sectors – including manufacturing, services, transportation, and telecommunications – which is heavily reliant on information technology.[1] This model is reshaping the organization and management of the entire value chain of consumer goods and putting in place a new infrastructure. What makes this business model possible is the real-time networking of products, processes, and infrastructure, as well as related customer services via the Internet. This enables rigid value chains to be transformed into highly flexible value networks.

The approach has been termed #Industry4.0 and is deemed to constitute a fourth industrial revolution. It is characterized by its interoperable design where machines, devices, sensors, and people are connected and can exchange relevant information in real time over the #InternetOfThings (IOT). This transparency enables dynamic, efficient production processes that can be optimized on the basis of different criteria such as cost, availability, and resource consumption. Software and machines operate autonomously and do not require complicated #Programming to meet new requirements, which makes it possible to react fast to individual customer requests. Individual parts of the chain "know" what they are, where they belong, how they need to proceed, and can interact with the production plant. The plant then decides by itself what should be done in accordance with priority and time frame. In these modular structured #SmartFactories the implemented software recognizes defects or mistakes at an early stage and is able to counteract them.[2]

Industry 4.0 is as yet a developing process. To work successfully, it will require a great deal of standardization and uniformity on an international scale. New forms of cooperation between companies across sectors both nationally and globally need to be created. The smart factory's highly flexible value networks call for the harmonization of #Interfaces (see key area #Encoding); that is, a reference architecture, a set of uniform definitions and methods. It necessitates a common structure and language for standardized description and specification of systems. Industry 4.0 brings many challenges to IT and data security, which can compromise the integrity of production processes. Similarly, it raises legal issues that need regulation, concerning data protection (corporate, employee, and consumer) and liability for automated systems.[3]

However, the greatest transformation that the new business models bring with them is the way in which labor is organized. Routine and low-skill jobs are increasingly threatened by #Automation, for

they are being taken on by intelligent machines and #Robots (see key area #MachineLearning). Employees are obliged to acquire a much broader range of skills which allow them to take action and make decisions that #Algorithms (see key area #Encoding) cannot. Considering these changing dynamics of labor, employees will need to be trained and qualified for new roles, be more flexible and mobile. This transformation has been termed #Work4.0.[4]
In this economy knowledge is the key resource in which everything is geared towards innovation. The changeover from a labor-based society to a knowledge society is imminent. Fewer people will be top wage earners, fewer people will have less (routine) work to do, and fewer people will do more (highly technical and highly qualified) work. Knowledge and know-how will be the new gold, the new oil. At one end of the spectrum, the workplace increasingly adapts to more flexible and dynamic structures that cater to individual needs in order to harness creativity. Yet only the top-end workers receive these benefits as well as profit from healthy and family-friendly working arrangements. The other end of the spectrum may resemble the manual labor factories for software engineering similar to the Silicon Valley accelerators.

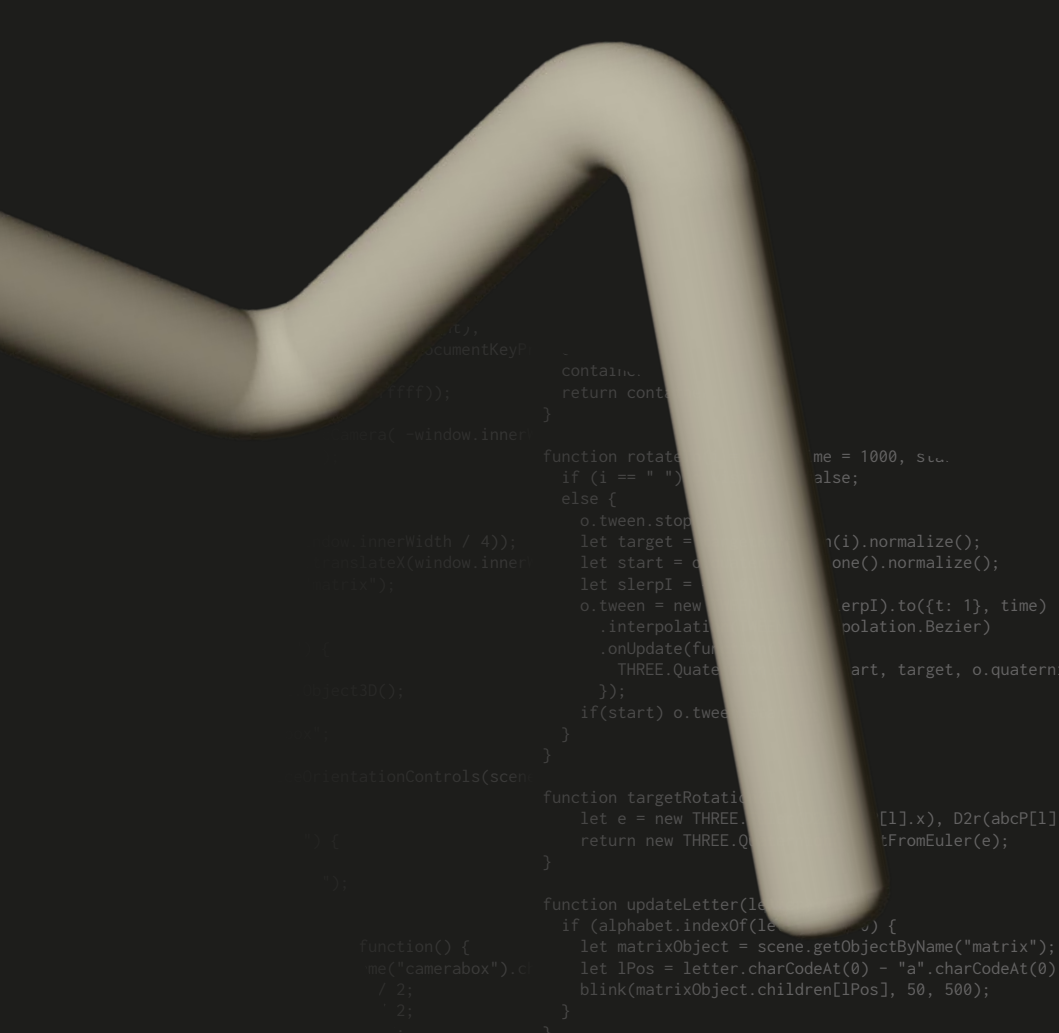
#AlgorithmicEconomy

#HighFrequencyTrading
#Bitcoin
#Cryptocurrencies
#Decrypt
#Blockchain



In a world where everything is becoming digital (our way of communication, our advertising, our leisure and workplaces), it was only a matter of time before money could be generated in a digital way. Banks and markets have been operating for decades using computerized algorithms and many customers have had digital access to their money for some time now. However, the matter at hand – #AlgorithmicEconomy – is more extensive and complex. Which impacts has the implementation of code had in our globalized economy? Which systems have appeared – or will appear in the future?

One of the first concepts that emerges when talking about the combination of economics, mathematics, and computer science is algorithmic trading, a practice widely used by investment banks and pension funds that utilize automated preprogrammed instructions to make decisions and execute transactions in the financial markets. This means that nowadays #Algorithms (see key area #Encoding) drive a great number of stock trades. Many systems of these automated activities fall into the category of #HighFrequencyTrading (HFT), which is characterized by such high speeds that a human could never carry them out in the same time nor even close to it.

As an alternative to this hegemonic system and its financialization, a new digital currency called #Bitcoin was released online in 2009, followed by many other digital cash currencies, such as Ethereum or Litecoin. But what makes #Cryptocurrencies different from traditional currencies? As its name implies, they are based on a cryptographic system,[1] which means that the code behind them is elaborated on a system that keeps information secret. Only the people – or more precisely, the programs – that know how to solve it, how to #Decrypt it, will have access to this information. Cryptocurrencies are also immaterial and decentralized. Unlike centralized banking, where governments control the currency values through the process of printing money, governments have no control over cryptocurrencies: their value circulates on the Internet without the regulating involvement of any intermediaries.

To understand the correlations, one has to look at the #Blockchain, the system behind cryptocurrencies. Blockchain is an open database that, in this case, stores a history of financial transactions. Single blocks contain various transactions, each of which is linked to a previous record in the chain. When someone purchases something with Bitcoins, a request in the form of a cryptographic puzzle is sent to and received by all the computers – known as miners – on the Bitcoin peer-to-peer network. When a miner solves a puzzle, a new block is added to the chain and it is rewarded with some Bitcoins. But earning Bitcoins is not the

only point of mining: the puzzles are so complex that every new block makes the previous ones and the whole chain a safer environment. Hacking the block-chain would require immense speed to alter just one transaction. With many miners adding blocks continuously, a vast amount of computing power would be needed.

Like other disruptive technologies born in the digital age, cryptocurrencies are challenging the way things have been done in economics so far, foreseeing a future in which middlemen would become obsolete. In a world run by blockchain technologies, new tools for business strategies and managing transfers would be developed, shifting "the control of money and information away from the powerful elites [...] to the people to whom it belongs."[2] While many people argue that these models will disrupt the centralized economic and political establishments, others say that they will severely impact our job market and only benefit those in the upper echelons of the workforce. It is not possible to predict the future, but to understand the world we live in and the economy we are building, we necessarily need to recognize and analyze the power of algorithms and computation.

1 The term cryptography derives from Greek κρυπτός, *kryptós,* which means "hidden" or "secret," and γράφειν, *graphein*, Greek for "writing." See Henry George Liddell and Robert Scott, *A Greek–English Lexicon*, Oxford University Press, 1984.

#VirtualReality

#HMD
#ComputerSimulatedEnvironments
#AugmentedReality
#ComputerGeneratedDesign
#Escapism

To understand the significance of *virtual* and #VirtualReality in the present context let us take a closer look at the rise of current usages of these terms. Virtual reality (VR) is understood as a technical term, as a medium that reproduces spatial experiences for its viewers – experiences of and in spaces that do not physically exist and cannot be explored by touch, for example, especially when other visual stimuli are blocked out (for example, by head-mounted displays, #HMD). In art, since ca. 1920, bodies that only appear to exist are referred to as virtual (e.g., Naum Gabo, *Konstruktion*, 1921). A rotating wire driven by an electric motor, for example, produces what looks like a three-dimensional figure on a disk. In the 1920s, experimental psychology and gestalt theory investigated this phenomenon in depth, for example, the stereo-kinetic effect. Kinetics and Op Art are its products. Since the term has been used in the context of computer technology the meaning relating to #ComputerSimulatedEnvironments has been added to most dictionary definitions as follows: simulated on a computer or computer network, or existing within a virtual reality.[1]

Thus we can conclude that "the virtual is a substitute – 'acting without agency of matter' – an immaterial proxy for the material. The term becomes a key marker of a secondary order in the relationship between the real and its copy, the original and its reproduction, the image and its likeness."[2]

In philosophy Henri Bergson, Gilles Deleuze, Félix Guattari, and Pierre Lévy all developed various concepts of the virtual. Bergson describes the immateriality of memory as virtual.[3] For Deleuze virtual is not opposed to real, but to actual – in this understanding virtual is a mode of reality.[4] Guattari describes virtual as one of "four ontological functors"[5] – the virtual, the actual, the real, and the possible.

The term "virtual reality" is relatively recent and was probably coined by Antonin Artaud in his book *The Theatre and Its Double*, first published in French in 1938.[6] Our current understanding of VR does not coincide with Artaud's usage of the term; the meaning has shifted over the last decades, and now the term is predominantly used for computer-aided interactive and immersive environments, together with #AugmentedReality, that are accessed via screened images and in many cases additional devices (such as HMDs).

Artists and engineers began to experiment with the medium in the 1980s (Myron W. Krueger, *Artificial Reality*, 1983) and contributed to its development of #ComputerGeneratedDesign. Especially in the 1990s applications and artistic experiments using VR proliferated and resulted in artworks. Although at that time the technology was not sufficiently developed for wider usage, with the wider availability of the hardware and various software for it, in the last few years more and more artists have started to work with VR as a medium.

The medium offers complete visual immersion; it not only opens a window, as framed images do, as Leon Battista Alberti claims in his treatise *On Painting* (1435). The Art of Immersion, however, actually pulls the observer into the image and not only opens a window as painting and framed art works do. VR is a gateway through which viewers in the real world enter and leave the virtual world. VR literally opens a door into another reality.

In the gaming industry and in medicine the technology is already widespread. Virtual models help surgeons, for example, to identify the safest and most efficient way to locate tumors and place surgical incisions. Psychologists and other medical professionals are using VR to enhance traditional therapy methods and find effective solutions for treatment of posttraumatic stress disorder (PTSD), anxiety, and social disorders. Real estate businesses and architects accompany their possible tenants or building contractors on walk-throughs of as yet nonexistent buildings.

VR technologies are becoming ubiquitous, not only because of the supreme #Escapism the medium offers, but also because of its practical and commercial potentials.

#GeneticCode

#DNA
#SourceCode
#Bioengineering
#Phenotype
#DNADataStorage
#Genotype

#DNA (deoxyribonucleic acid) is known to contain the #SourceCode. #GeneticCode is the set of rules by which information encoded within genetic material (DNA or mRNA sequences) is translated into proteins by living cells.

The description of genetic code began in the 1950s. By 1953 it was clear that the genetic information in DNA, a macromolecule forming a double helix (James Watson, Francis Crick), is made up of four chemical bases: adenine (A), guanine (G), cytosine (C), and thymine (T). At this time the central dogma of molecular biology became that DNA contains the code for the construction of proteins that catalytically and structurally "execute" life.[1]

The metaphors and phrasing used in molecular biology were strongly influenced by #Cybernetics (see key area #Machine-Learning) and information theory that became influential in the late 1940s and 1950s, exactly when genetics started to spread its wings.[2]

DNA and RNA were called "informational molecules" or "tapes" governed by the rules of information processing.[3] Genetic code was also compared to a computer program, for example, "organs, cells and molecules are united by a communication network."[4]

To decipher the code of the biological "Book of Life," was a central issue in molecular biology, and researchers were racing to crack it. The Human Genome Project (HGP, 1990–2003) was an international scientific endeavor with the goal of determining human #Genotype[5], the sequence of nucleotide base pairs that make up human DNA. The private research project of Craig Venter (Celera Corporation) has worked with automated DNA sequencing since 1998.

The developments in molecular biology facilitated new fields of engineering. #Bioengineering "is the manipulation of an organism to produce non-native molecules (such as drugs or proteins)."[6] Recombinant DNA technology, a method originally invented by Stanley N. Cohen and Herbert Boyer in the 1970s to insert human DNA into bacteria to produce a recombinant version of insulin for the treatment of diabetes, is the key for this discipline. The latest developments in the field are genome editing methods; CRISPR/Cas9 recently got the most publicity. Genome editing allows researchers to modify any genomes, including human, with wide application possibilities.[7] The method, just like genetic engineering in general, raises ethical questions.

It has been recently discovered that DNA molecules can store any data (#DNADataStorage). Textual and visual information, even moving images, can be converted to binary then to genetic code[8], which has allowed researchers to encode in a decodable way, for example, a series of frames from Eadweard Muybridge's *Human and Animal Locomotion* in bacterial DNA.

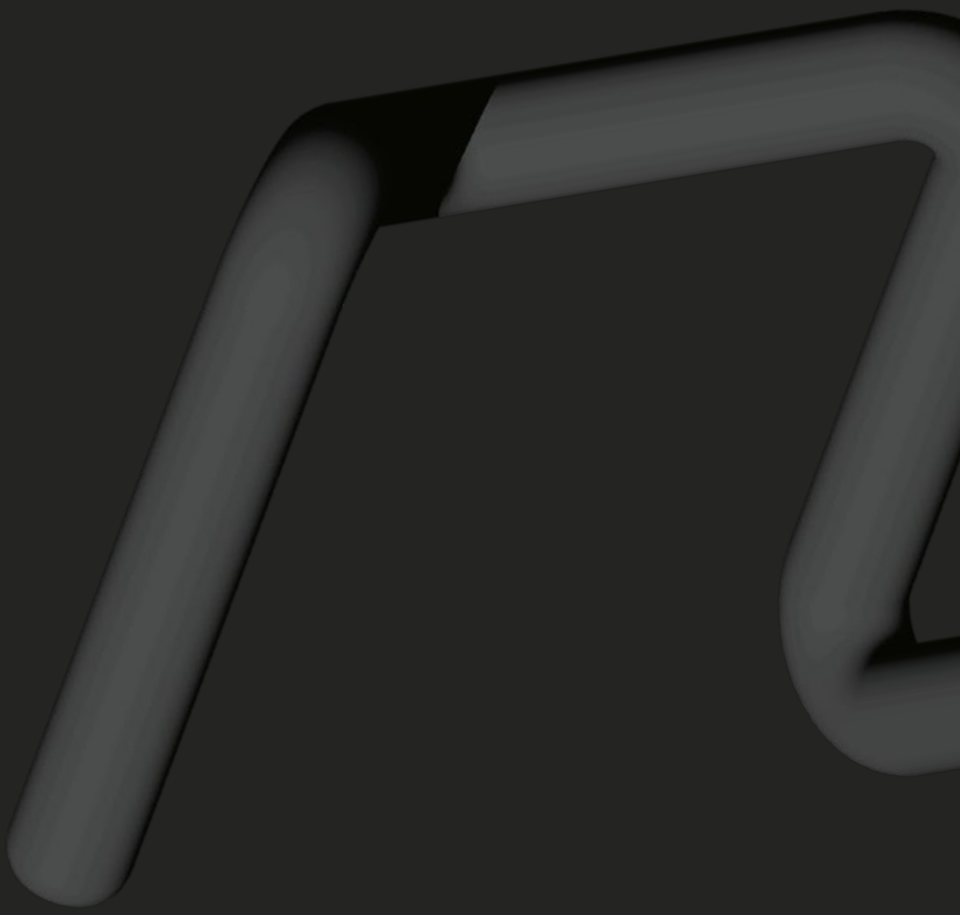
Signal Codes and Machine Codes

Franz Pichler



#GenealogyOfCode
#Binary
#Computing
#NumeralSystem

Codes:
Mathematical Objects for Transmitting Messages

Signal codes

Signals enable communication between people via machines. They make it possible to exchange messages, thereby conveying information. Every signal has technical, material, and mathematical abstract components. For example, each Morse signal that is transmitted from a sender to a recipient is comprised of a series of states of electrical energy that can also be expressed mathematically as the dots and dashes of the Morse alphabet. The Morse code is the essential part of the exchange of messages. The electrically generated signal executes and transmits the Morse code via the technological apparatus available. Certain technical, physical devices are necessary in order to generate signals and to transmit, save, and receive them. The technical means used for optical, acoustic, mechanical, magnetic, and electrical signals can be generated by means of physics, optics, acoustics, mechanics, magnetism, electricity, and electromagnetic waves. In principle, all of these types of signals can be used to display one and the same signal code.

The assignment of code symbols belonging to a signal is called encoding. The transformation of one signal into another is known as signal conversion. Analogue signals are those for which the associated mathematical description requires the use of a system of real numbers. Analogue signals are found predominantly in the measurement of physical states. The signals that are generated by musical instruments or by human voices are also examples of analogue signals. Digital signals are those that can be expressed mathematically through a system of whole numbers. Together with their associated digital codes, digital signals currently make the effective exchange of messages possible by means of microelectronics, computer technology, and information technology. They also provide the basis for data to be processed by computers.

Codes:
Mathematical Objects to Generate Dynamic Processes

Machine codes

In everyday life and the workplace, we are constantly confronted with dynamic processes. We designate processes as dynamic that take on different states over the course of time. For example, consider the dynamic process that takes place in connection with the purchase of a ticket from a ticket machine. This begins with the initial state; the ticket machine is directed toward an end state in temporal succession through incremental signals that are sent by clicking, which culminates in the issue of a ticket after payment has been made. Another example of a dynamic process is the weather forecast shown on television, in which the weather conditions in geographic areas are shown in chronological order for successive days of the week. The implementation of work plans, in which the state of the work at given times is shown, can also be considered an example of a dynamic process. We live in a world in which we are surrounded by a multitude of dynamic processes. Ultimately, one can even see oneself as a dynamic process – albeit a highly complex one.

Generally speaking, every dynamic process is a conglomerate of parts: material, energy, and information. Dynamic processes that primarily relate to information, however, are the focus of the *Open Codes* exhibition. This is a matter of dealing with the mathematical foundations, the mathematical system that is essential for the generation of dynamic processes. The machine codes are responsible for this at the exhibition. Machine codes in this sense lead us into the world of the mathematical analysis devised by Isaac Newton and Gottfried Wilhelm Leibniz; the world of mechanics from Leonhard Euler to Joseph-Louis de Lagrange and Pierre-Simon Laplace; and also the world of automata, calculators, and computers created in the modern era, plus the world of algorithms created through programming. Charles Babbage, Alan Turing, Kurt Gödel, Konrad Zuse, Howard Aiken, John von Neumann, Claude E. Shannon, and Gustav Knuth are all significant here, to name some important pioneers. Mathematically, the machine codes at the exhibition have to do with areas such as differential equations, difference equations, mathematical logic, Boolean algebra, finite automata, cellular automata, Petri nets, and algorithms. For all of these areas there are associated mathematical theories, which can be used in dealing with dynamic processes and the associated machine codes. The programming systems for social networks such as Facebook, as well as operating systems for personal computers (such as smartphones) and the application systems for them (e.g. Google) are current practical examples of machine

codes. Because of the business models associated with them, in many ways these represent counterexamples to the concept of "open codes" in an information technology sense. They are, however, addressed in the *Open Codes* exhibition.

Codes: Historical Technical Components and Writings

Building blocks for "open codes"

Besides its focus on art, science, and society, the *Open Codes* exhibition also addresses the historical development of the technical components and systems necessary to generate, transmit, and process codes. These are: mechanical or electrical counting mechanisms; memory modules created by mechanical, magnetic, or electronic technology; and combinatorial circuits ranging from simple routers with plug contacts to the microelectronic gates and microprocessors in use today. Because of the historical significance of Morse code, the exhibition devotes particular attention to this system. With regard to the development of computers, various forms and models of calculating machines are exhibited in the exhibition. The technical and mathematical development of codes and their use as signal codes or machine codes is presented through seminal texts, from Ramon Llull's Ars Magna and Friedrich von Knaus's book on the miraculous writing automata he constructed to the mathematical works of George Boole, Claude E. Shannon, and John von Neumann.

Franz Pichler

In the *Open Codes* exhibition around eighty objects from the Pichler Collection are on show. Large parts of this collection were added to the ZKM | Collection in 2011.
